Abstract
We analyzed the complete mitochondrial genome of the Asian tropical hornet *Vespa affinis* from Ishigaki Island, Japan. It consisted of a circular molecule with 19,109 bp, which is larger to other hornet species e.g. *V. velutina*. We predicted the genome contained 13 protein-coding, 22 tRNA, and two rRNA genes, along with one A+T-rich control region. The repetitive sequences were confirmed at multiple positions in the non-coding genes. The initiation codons ATA was found in one, ATG in seven, ATT in five genes, while the termination codons TAA and TAG were observed 11 and two genes, respectively. The average AT content of the genome was 78.4%.

Keywords
Hornet, Illumina sequencing, repetitive sequence, monogynous, polygynous.

There are 22 hornet (genus *Vespa*) species (Archer 2012; Perrard et al. 2013) and these have become an important model group for research into social systems such as; worker altruistic behaviors, reproductive conflict, evolution of the queen number and development of sociality (Matsuura 1990; Foster and Ratnieks 2001). More recently the accidental spread of the ‘Yellow-legged hornet’ *Vespa velutina* into Korea and France is causing major problems for beekeepers (Takeuchi et al., 2017). The tropical hornet *Vespa affinis* is distributed throughout the subtropical and tropical regions of Asia (Archer 2012). Normally the *V. affinis* colony is founded by a single queen, although some
nests contain multiple queens in tropical regions (Matsuura and Yamane 1990; Martin 1995a, b), an unusual trait among the hornets. To date there has been limited analysis of mitochondrial DNA from hornets (Takeuchi et al. 2017), so hampering a detailed knowledge about their population genetic structure, intraspecific phylogeny relationships and genetic diversity. Therefore, to help resolve this issue we analyzed the complete mitochondrial genome of the hornet *V. affinis*.

A single adult worker was collected from a colony on Ishigaki Island, Okinawa Prefecture, in the sub-tropical region of Japan (the specimen was stored in the National Museum of Nature and Science, Japan, accession number: NSMT-I-HYM 75315). Genomic DNA was isolated and sequenced using Illumina’s Next Seq 500 (Illumina, USA). The resultant reads were assembled and annotated using the MITOS web server (Bernt et al. 2013), MEGA6 (Tamura et al. 2013), and GNETYX v.10 (Genetyx Corporation, Japan). The phylogenetic analysis was performed using TREEFINDER (March 2011) (Jobb et al. 2004) based on the nucleotide sequences of the 13 protein-coding genes.

The *V. affinis* mitochondrial genome forms a 19,109 bp-long closed loop (accession number AP018371). Although it is ~2400 bp shorter than the *V. velutina* genome it has a very similar genomic organization, since it is comprised of 13 protein-coding, 22 putative tRNA, and two rRNA genes, as well as an A+T-rich control region. The average AT content of the 13 protein-coding genes was 78.4%, similar to the 82% found in *V. velutina* (Takahashi et al., 2017). The *V. affinis* genome, was predicted to have nine protein-coding and 14 tRNA genes on the heavy strand and four protein-coding, eight tRNA, and two rRNA genes on the light strand. The genes ND4 and ND4L shared seven nucleotides. Of the 13 protein-coding genes, the initiation codon ATA was found in one, ATG in seven, and ATT in five genes, while the termination codon TAA and TAG were observed in the protein-coding genes ND4 and Cytb respectively.

Phylogenetic analysis using the 13 mitochondrial protein-coding genes from 11 closely related taxa of Vespidae (Cameron et al. 2008; Song et al. 2016; Wei et al. 2016; Zhou et al. 2016; Fan et al. 2017; Haddad et al. 2017; Kim et al. 2017a,b; Takahashi et al. 2017) suggested a close relationship between *V. affinis* and *V. mandarinia*, which it not fully supported by the combined analysis based on 45 morphological characters and six genes (Perrard et al. 2013). Although more high resolution sequence data from more species may help resolve these differences. Finally, non-coding repetitive sequences in the mitochondrial DNA of *V. affinis* were confirmed at multiple positions between the 13 protein-coding genes and these regions will help to develop a suite of specific primers for the estimation of genetic relationship and genetic diversity.
