Autism Spectrum Disorder, Bestiality and Zoophilia: A Systematic PRISMA Review

Abstract

Purpose: There remains a lack of knowledge surrounding paraphilic or deviant arousal sexual behaviours in individuals with ASD (Kellaher, 2015). The aim of the present systematic review is to explore the literature for any empirical study, case study or discussion/review paper surrounding individuals with ASD and zoophilia or bestiality. **Methodology:** A systematic PRISMA review was conducted. **Findings:** This systematic review highlighted only a small number of papers which have looked at zoophilia or bestiality in individuals with ASD. Only one article was identified as being relevant in the present review, three further articles included a description of a case involving someone with ASD who engaged in zoophilia or bestiality and another paper, although not the focus of the study, found one person with Asperger's Disorder who had several paraphilias including olfactophilia, podophilia and zoophilia in a sample of 20 institutionalized, male adolescents and young adults with Autistic Disorder (AD) and borderline/mild mental retardation (MR). All the case studies clearly highlight some of the ASD symptomology that can contribute to engaging in bestiality or zoophilia. **Practical Implications:** It is important that individuals with ASD have access to appropriate and timely sex education and that parents are supported by healthcare professionals to engage with their children with ASD in such interactions across the autism spectrum irrespective of the parent's expectations. **Originality:** To the authors knowledge, this is the first review on ASD in relation to bestiality and zoophilia.

Keywords: Autism spectrum disorders; ASD; asperger's syndrome; bestiality; zoophilia; zoosexual behaviour; zoophilism; zooerasty; zooerastia; bestiosexuality.

Introduction

Zoophilia and Bestiality

Zoophilia is a paraphilic disorder with intense recurrent sexual fantasies, urges and behaviours involving animals. In the fifth edition of Diagnostic and Statistical Manual (DSM-5) zoophilia is categorised under “other specified paraphilic disorder” in the DSM-5. The DSM-5 classifies paraphilia as “any intense and persistent sexual interest other than sexual interest in genital stimulation or preparatory fondling with phenotypically normal, physically mature, consenting human partners” (APA, 2013, pp. 685). The DSM-5 makes a distinction between a paraphilia and a paraphilic disorder. It states that a paraphilic disorder “is a paraphilia that is currently causing distress or impairment to the individual or a paraphilia whose satisfaction has entailed personal harm, or risk of harm, to others” (APA, 2013, pp. 685–686). Additionally, zoophilia is classified as disordered if this behaviour is ego-dystonic and harmful to oneself or others. In the DSM-5, there are eight specific paraphilias detailed, namely, voyeuristic, exhibitionistic, frotteuristic, sexual masochism, sexual sadism, pedophilic, fetishistic and transvestic.

Two categories were added in the DSM-5. These were “other specified paraphilic disorder” (this is replacing paraphilia not otherwise specified) and unspecified paraphilic disorder. These are used when the assessor makes the decision to describe just the diagnostic class. ‘Other specified paraphilic disorder’ includes, for instance, zoophilia (animals), scatologia (obscene phone calls), necrophilia (corpses), coprophilia (faeces), klismaphilia (enemas), urophilia (urine) (APA, 2013, pp. 685, 705). Shaffer and Penn (2006) also describe a variety of zoophilia types in their paper. For instance, necrobastialism (arousal from having sex with dead animals); avisodomy (breaking the neck of a bird while penetrating it for sex); anolinguus (arousal from licking lizards); phthiriophilia (attraction to lice) and musophilia (arousal from mice). A paraphilic disorder involving animals can be diagnosed under the “other specified paraphilic disorder” category (Holoyda, 2017). Frequently the behavior of sexual contact with the animal(s) occurs in the individuals place of residence or on the farm or stable which affords the individual some degree of privacy, reducing the risk of being reported. The animals which are found to be most commonly used for sex are dogs and horses (Beetz, 2004). In the literature there have been descriptions of over 100 unique paraphilias (Federoff, 2010). The revisions to the DSM-5 (APA, 2013) now makes it possible for an individual to engage in consensual atypical sexual behaviour without it being considered to be a mental disorder. The prevalence in the general population is unknown and is believed to be rare (Holoyda, & Newman, 2014).

1
2
3
4
5 Bestiality is a term which is used to describe any sexual act which occurs between a human
6 and an animal. Saying that someone engages in bestiality is different to giving a diagnosis of zoophilia.
7 It also fails to explain why someone engage in sexual intercourse with an animal. As explained by
8 Holoyda and Newman (2016), there are a number of different motivations for engaging in sexual
9 intercourse with animals (Holoyda, Sorrentino, Friedman, & Allgire, 2018). Studies investigating
10 bestiality are limited to specific subgroups such as forensic samples or self-identified zoophiles. It is
11 not fully understood what the prevalence of bestiality is in the general population (Holoyda,
12 Sorrentino, Friedman, & Allgire, 2018). As discussed by Beetz (2004), Miletski (2002) and Beetz
13 (2002) highlighted the distinction between zoophilia and bestiality. Zoophilia refers to an emotional
14 attachment to animals which is associated with a preference for having animals as sexual partners or
15 that includes a sexual attraction. Bestiality is a term which is used to describe any sexual contact of
16 humans to animals or physical contacts to animals that result in sexual excitement for the human who
17 is engaged in these acts. Crucially, these types of relations between a human and an animal may occur
18 in combination and there is nothing to suggest that they should be treated as totally distinct categories
19 (Miletski, 2002) (Beetz, 2004).

31 *Issues with the diagnostic criteria*

32
33
34 Beech and colleagues (2016) highlight the significant controversy exists surrounding what a paraphilia
35 actually is and when an unusual sexual interest becomes a mental disorder (Moser, 2009). There is a
36 lack of agreement regarding what is “normal” sexual behaviour. As a result, there exists no useful
37 boundary to consider when making decisions regarding what denotes a sexual mental disorder (e.g.,
38 Frances & First, 2011). Indeed, the APA had not offered a definition of normal sexual behavior, in
39 contrast with paraphilic interests until the publication of the DMS-5 (Beech, Miner, & Thornton,
40 2016). Moreover, due to the ‘malleability’ of sexual norms across time and cultures, it is difficult to
41 define the concept of “deviant” sexual behaviour in any absolute way (McManus et al., 2013). The
42 revisions to the DSM-5 aimed to partly address this issue by including ‘disorder’ after every paraphilia
43 diagnosis. This enables people to engage in (some) atypical sexual behaviours without it being labelled
44 a mental disorder. In the DSM a disorder is classified as a “behavior that causes mental distress to a
45 person or makes the person a serious threat to the psychological and physical wellbeing of other
46 individuals” (<http://www.dsm5.org/Documents/Paraphilic%20Disorders%20Fact%20Sheet.pdf>, p. 1)
47 (Beech et al., 2016, or more discussion of the problems with paraphilias in the DSM-5 see Fedoroff,
48 Di Gioacchino, & Murphy, 2013).

Classification of zoophilia

Aggrawal (2011) proposed a ten-tier classification scheme of bestiality based on his necrophilia classification scheme in which he categorized behaviours from least pathologic to most pathologic. with those individuals “pathologically less deviant” belonging in Class I (role players) and those more deviant belonging in Class X (exclusive zoophiles). Notably, he categorized the “exclusive zoophile,” or somebody who only engages in sex with animals, as the most pathologic. DSM criteria (American Psychiatric Association, 2013) have solely focused on atypical sexual interest when establishing a diagnosis rather than the meaning of or motivations underlying an individual's sexual behaviours and interests. Specifically, Class I zoosexuals: humaneanimal role-players (individuals in this category do not use animals for sex. They are mere role-players and would rather that their human partners act as animals during sex, as the thought of having sex with animals causes them great excitement); and Class X zoosexuals (this class includes individuals who are exclusively zoosexuals. Sexual intercourse is possible only or mostly with animals. There is virtually a complete exclusion of human partners) (Aggrawal, 2011). In Aggrawal’s (2011) ten-tier classification scheme, zoophilic Classes III through X all would come under the single diagnosis of Paraphilia Not Otherwise Specified–Zoophilia or Other Specified Paraphilic Disorder–Zoophilia. Holoyda (2017) has argued that using Aggrawal’s ten-tier classification system to classify bestiality behaviours may be useful for forensic and clinical professionals in obtaining a greater understanding of what specific sex acts an individual engages in. However, it is important to point out that although “defining the specific sex acts related to bestiality can be instructive, consideration of individuals’ motivations for engaging in bestiality may prove more useful to a forensic psychiatric evaluator” (Holoyda, 2017, pp. 543).

Psychiatric Disorders and Zoophilia

Yakeley and Wood (2014) pointed out that there are relatively few studies investigating the prevalence of paraphilias in psychiatric populations. However, one of the few studies (Marsh, 2010) found that 13.4% of psychiatric inpatients had a DSM-IV paraphilia (Diagnostic and statistical manual of mental disorders, 4th ed., Text Revision. Washington, DC: Author. American Psychiatric Association, 2000). Compared to patients with no paraphilias, patients with paraphilias were found to be more likely to have been admitted to hospital before and to have made a suicide attempt. Turning to forensic populations, there are a number of studies which have found that paraphilias are relatively common in forensic populations. For instance, studies have found rates as high as between 25 and 75% in sex offenders (Raymond, 1999; Dunsieith, 2004). In an earlier study, the prevalence of bestiality (both

1
2
3 actual sexual contacts and sexual fantasy) was examined in a group of 20 psychiatric inpatients
4 compared to the prevalence of bestiality in two control groups (one being 20 medical inpatients and
5 the other group 20 psychiatric staff members). Findings showed that there was a significantly higher
6 prevalence rate (55%) of bestiality in the psychiatric patients compared with the control groups (10%
7 and 15%, respectively) (Alvarez & Freinhar, 1991).

9
10
11
12

13 14 *Autism Spectrum Disorders (ASD)*

15
16
17 Autism spectrum disorder (ASD) is a neurodevelopmental condition. ASDs are characterised by social
18 communication and social interaction difficulties and restricted, repetitive behaviours or interests
19 (RBRI) (APA, 2013). It is worth pointing out here that RBRI characterises behaviours that can
20 include repetitive motor movements, sensory reactions, rituals, routines and restricted interests. In the
21 DSM-5 (APA, 2013) the subtypes of ASD have been abandoned (e.g., autistic disorder and Asperger
22 disorder) and there is now a single category of ASD (Maenner et al., 2014). Numerous studies have
23 found that approximately four males fulfil the diagnostic criteria for ASD for every female (e.g.,
24 Fombonne 2009; Szatmari, Chawarska, Dawson, Georgiades, Landa et al., 2016; Lord, Rutter, & Le
25 Couteur, 1994; Volkmar, Szatmari, & Sparrow, 1993; McLennan, Lord, & Schopler, 1993; Brugha,
26 McManus, Bankart, Scott, Purdon et al., 2011; Loomes, Hull, & Mandy, 2017). Many hold the belief
27 that the new criteria will led to a decrease in the number of individuals who received a diagnosis of
28 ASD (e.g., Kim et al., 2014; Maenner et al., 2014; McPartland, Reichow, & Volkmar, 2012; Taheri &
29 Perry, 2012).
30
31
32
33
34
35
36
37
38
39

40
41 As highlighted by Kulage and colleagues (2014) in their paper, ASD in the DSM-5 now
42 includes only two main behaviour categories because social interaction and communication have been
43 collapsed into one criterion. To fulfil the diagnostic criteria for ASD, an individual must meet four
44 broad criteria which consist of meeting all of the three distinctions of the social communication and
45 interaction (SCI) criteria and also two out of four distinctions of the RRBI criteria. With the changes
46 in the DSM-5 there are now significantly less ways to meet the diagnostic threshold for ASD (Kulage,
47 Smaldone, & Cohn, 2014). There are just 11 possible combinations of ASD criteria (McPartland et al.,
48 2012). However, there are others (e.g., Huerta, Bishop, Duncan, Hus, & Lord, 2012; Swedo et al.,
49 2012) who would disagree that the new DSM-5 criteria for ASD will result in a decrease in ASD
50 diagnoses and contend instead that the changes to the diagnostic criteria in the DSM-5 will make no
51 impact on the prevalence and will actually result in an increase in the accurate identification of ASD
52 compared to the diagnostic criteria in the earlier versions of the DSM (Haney, 2016).
53
54
55
56
57
58
59
60

1
2
3 In terms of the genetic basis for ASD, as many as eight hundred eighty-one genes have been
4 identified as being implicated in the etiology of ASD, with a minimum of one from each chromosome
5 (Butler, Rafi, Hossain, Stephan, & Manzardo, 2015 (<https://gene.sfari.org/>)). Most cases of ASD have
6 a genetic etiology which is unknown. There have also been a number of prenatal or perinatal
7 environmental factors which have been found to contribute to the disorder. However, the exact
8 mechanisms of these factors remain unclear (e.g., Geschwind, 2011; Dean, Harwood, & Kasari, 2017;
9 Ferri, Abel, & Brodtkin, 2018). It has been posited that risk genes may interact with sex-specific
10 pathways which may be related to hormones or immune function, as opposed to the risk genes being
11 sex-specific themselves (Werling, Parikshak, & Geschwind, 2016; McCarthy & Wright, 2017, see also
12 Gillberg, Fernell, Kočovská, Minnis, Bourgeron, Thompson, & Allely, 2017).

21 *ASD and Deviant Sexual Behaviour*

22
23
24 Over the last decade, there has been an increasing number of empirical studies exploring sexuality
25 among individuals with ASD. The findings from these studies are “dispelling antiquated notions that
26 ASD individuals are asexual, sexually unknowledgeable and inexperienced, and/or disinterested in
27 relationships” (Kellaher, 2015, pp. 24). There is still much research needed to investigate paraphilic or
28 deviant arousal sexual behaviours in individuals with ASD (Kellaher, 2015). Studies have shown
29 adolescents and adults with high-functioning ASD have just as much capacity for sexual behaviour as
30 individuals without an ASD diagnosis (Gilmour, Schalomon, & Smith, 2012; Dewinter, Vermeiren,
31 Vanwesenbeeck, Lobbestael, & Van Nieuwenhuizen, 2015). Before such research, it was believed that
32 individuals with ASD had little or no sociosexual experiences as a result of core social impairments
33 and asexuality or inappropriate sexual behaviours (e.g., Wing, 1981; Ruble, & Dalrymple, 1993).
34 Dewinter and colleagues have argued that, in individuals with ASD, specific sensory interests may
35 contribute to sexual behaviours (Dewinter et al., 2015, see also Allely & Creaby-Attwood, 2016).

36
37
38 There are only a handful of systematic studies investigating paraphilias in individuals with
39 ASD (Hellemans, Colson, Verbraeken, Vermeiren, & Deboutte, 2007; Fernandes, Gillberg, Cederlund,
40 Hagberg, Gillberg, & Billstedt, 2016; Schöttle, Briken, Tüscher, & Turner, 2017). The majority of
41 publications are case studies of individuals with ASD who exhibit a paraphilia or deviant sexual
42 behaviour (e.g., Kobayashi, 1991; Bowler & Collacott, 1993; Chesterman & Rutter, 1993; Cooper,
43 Mohamed, & Collacott, 1993; Milton, Duggan, Latham, Egan, & Tantam, 2002; Silva, Leong, &
44 Ferrari, 2003; Coskun, & Mukaddes, 2008; Dozier, Iwata, & Worsdell, 2011; Early, Erickson, Wink,
45 McDougale, & Scott, 2012; Kolta & Rossi, 2018). In their paper, Dozier and colleagues (2011)

1
2
3 described the case of Alex, a 36-year-old man with an ASD diagnosis. He exhibited very poor
4 expressive language ability. Alex had a 20-year history of inappropriate sexual (masturbatory)
5 behaviour (ISB). This behaviour he displayed consisted of dropping to a prone position close to another
6 person's feet and proceeded to gyrate his pelvis on the floor. Following functional analysis, Dozier and
7 colleagues found evidence which indicated that Alex engaged in bizarre sexual behaviour when he
8 was in the company of women who are wearing sandals (Dozier et al., 2011). To date, there have been
9 no published case reports involving females with ASD who are engaging in paraphilic or paraphilic-
10 like behaviours (or deviant sexual behaviours). The case reports on females which are available seem
11 to focus on gender dysphoria or masturbatory issues which are not deviant sexual behaviours (Kellaher,
12 2015). It is also important to point out that nearly all case studies involving males with ASD who are
13 engaging paraphilic behaviours also present with some type of cognitive impairment (Schöttle, Briken,
14 Tüscher, & Turner, 2017). How much the ASD symptomology contributes to the paraphilic behaviours
15 in these cases is unclear.

28 *Present Study*

29
30
31 There still remains a lack of knowledge surrounding paraphilic or deviant arousal sexual behaviours
32 in individuals with ASD (Kellaher, 2015). The aim of the present systematic review is to explore the
33 literature for any empirical study, case study or discussion/review paper surrounding individuals with
34 ASD and zoophilia or bestiality.
35
36
37
38
39
40

41 **Methods**

42
43 A total of five internet-based bibliographic databases were searched in order to identify studies which
44 explored ASD in relation to zoophilia (including case studies as well as empirical studies). The five
45 databases included: PsycARTICLES Full Text, [Database Field Guide] AMED (Allied and
46 Complementary Medicine) 1985 to May 2019, [Database Field Guide] PsycEXTRA 1908 to April 16,
47 2019, [Database Field Guide] PsycINFO 1806 to April Week 5 2019, [Database Field Guide] Ovid
48 MEDLINE(R) and Epub Ahead of Print, In-Process & Other Non-Indexed Citations and Daily 1946
49 to May 03, 2019. The search on the five electronic databases was performed on the 10th May 2019.
50
51 The search adhered to PRISMA guidelines (Liberati et al., 2009; Moher, Liberati, Tetzlaff, & Altman,
52 2009). The search was not restricted by date. Search terms were applied to title. The following search
53 criteria were entered into the five databases: (ASD or "autis* spectrum disorder*" or autis* or "autis*
54
55
56
57
58
59
60

spectrum condition*" or asperger*).m_titl. AND (bestiality or zoophilia* or zoosexual* or zoophilism* or zooerasty or zooerastia* or bestiosexualit* or bestials or bestialities or zoophile* or zoophilic* or zoosadism or bestialsadism).m_titl.

This search returned two articles. Following the removal of duplications there was one article. This one article was found to be relevant. As well as the searches carried out on the five databases listed above, a variety of permutations of the search terms entered into the databases were entered into Googlescholar. Googlescholar was searched thoroughly for any potentially relevant articles not identified through the search carried out on the five databases. Some examples of the search term groupings included: ASD AND bestiality; autism AND bestiality; autism AND zoophilia; asperger's syndrome AND bestiality; asperger's syndrome AND zoophilia and autism AND zoophiles. This resulted in a further four relevant articles which were identified as being relevant to the present review as they both included a description of a case involving an individual with ASD who had engaged in zoophilia or bestiality (see Figure 1. For PRISMA Flow Diagram of this process). Lastly, given the relatively lack of research in this area, the present systematic review adopted an inclusive approach. There were no exclusion criteria for the papers identified which investigated ASD in relation to bestiality or zoophilia or included a discussion of a case study of someone with ASD who had engaged in zoophilia or bestiality. All forms of sources will be considered for inclusion including academic peer reviewed articles, reports, discussion papers, book chapters, conference abstracts, dissertations, etc. In all the papers which were relevant for inclusion in the present review the reference section was examined for any potentially relevant articles.

Results

Only one article was identified as being relevant in the present review (Chandradasa & Champika, 2017), three further articles included a description of a case involving someone with ASD who engaged in zoophilia or bestiality (Jones, 2007; Freckelton, 2013; Kellaheer, 2015) and another paper, although not the focus of the study, found one person with AD who had several paraphilias including olfactophilia, podophilia and zoophilia in a sample of 20 institutionalized, male adolescents and young adults with Autistic Disorder (AD) and borderline/mild mental retardation (MR) (Hellemans, Roeyers, Lepiae, Dewaele, & Deboutte, 2010). The relevant information will be discussed in turn.

Firstly, Chandradasa and Champika (2017) reported in their paper a case of SB a 17-year-old male adolescent from Sri Lanka with high functioning ASD presenting with features of zoophilia. He

1
2
3 had intelligence and academic abilities within the normal range. The amount of time that SB was
4 spending at his grandparents' cattle house had been increasing. One day he was discovered
5 masturbating close to the cows and was also later found engaging in penetrative sex with a heifer.
6 Following his parent's discovery of his deviant sexual behaviours, they sought traditional healing for
7 SB known as 'thovil' which is a demonic ritual of exorcist nature. The purpose of thovil is to chase
8 away any malevolent spirits which are believed to give rise to states of mind and body which are
9 pathological (Kurupparachchi & Rajakaruna, 1999). The clinical evaluation found that SB, over the
10 previous 12 months, "had recurrent, intense sexual fantasies about having sexual intercourse with
11 cattle, watching them mate and masturbating while observing them" (Chandradasa & Champika, 2017;
12 pp. 487).

21 According to Aggrawal's ten-tier classification scheme, SB's behaviour could be categorised
22 as class VII which refers to individuals who are regular zoophiles. They do not prefer intercourse with
23 humans and have a preference for sex with animals. He had no history of having had any romantic or
24 sexual relationship with another human. SB reported that he had viewed online human pornography.
25 However, he reported that, compared to watching animals, he did not get the same enjoyment from it.
26 SB did not report having any sexual interest in non-living objects, children or adult males. He had
27 significantly more interest in animals when compared to adult females. He preferred sexual fantasies
28 and behaviours related to animals. The conclusion from the clinical evaluation with SB was that he
29 fulfilled the DSM-5 diagnostic criteria for ASD and for other specified paraphilic disorder. A normal
30 sex hormone profile was found. For more than six months, SB had experienced 'recurrent intense
31 sexual fantasies, urges and behaviours' related to animals. The decision made for treatment was a
32 combination of cognitive-behaviour therapy and a selective serotonin reuptake inhibitor (Chandradasa
33 & Champika, 2017). Chandradasa and Champika (2017) argued that SB's persistent social difficulties
34 (which was part of his ASD symptomology) played a contributory role in the development of his
35 paraphilic disorder. This sexually deviant behaviours caused SB significant levels of distress.

48 In the paper by Kellaher (2015), she discusses a case where she evaluated a young man with
49 ASD whose interest in wolves as a child transformed into a preferential canine zoophilia as an
50 adolescent. He began during puberty, masturbating to images of females who were dressed up like
51 wolves – individuals who dress up like animals are referred to as "furies". Not long after, he started
52 watching online hardcore bestiality videos involving dogs. He was eventually arrested after having
53 entered into the yard of a stranger and masturbating as he touched a dog. He admitted that, as a child,
54 he had an interest in wolves which was insatiable. He was particularly attracted to the look of their soft
55
56
57
58
59
60

1
2
3 fur. When he was an adolescent, he attention was drawn to the scrotums of large dogs and he
4 experienced urges to touch the dogs' scrotums. He reported feeling excited sexually by looking at and
5 touching the fur and scrotum and soft fur of a large dogs that are wolf-like. For his sexual arousal, he
6 was particularly interested in the sensory parts of 'the whole' for his sexual arousal – the large scrotum
7 most notably. This is common in individuals with ASD. This focus on sensory parts of 'the whole'
8 was what subsequently contributed to his offending behaviour (Kellaher, 2015).
9
10
11
12
13

14 In his paper, Freckelton (2013) discusses the case of Director of Public Prosecutions v HPW
15 (2011) where the Victorian Court of Appeal heard an appeal which was brought by the prosecution
16 who contended that the sentencing judge at first instance had incorrectly identified a causal relationship
17 between HPW's Asperger's Disorder (AD) and his sexual offending, had "erred in imposing a
18 manifestly inadequate sentence and had inadequately cumulated the penalties he imposed for a
19 significant number of sex offences" (Freckelton, 2013, pp. 162). In this first instance, he was found
20 guilty of eight charges (three of these eight charges were representative of numerous occasions where
21 he had carried out sex offending against his biological daughter when she was 11 and 12 years of age.
22 The sex offending committed against his biological daughter involved numerous occasions of oral,
23 digital and anal penetration in addition to instances of masturbation and of getting the family dog to
24 lick his daughter's vagina. HPW admitted sodomising his daughter when the police interviewed him
25 and he said that it was "just as an experiment" and that "it was just sexual gratification for myself".
26 He also told police that he was "probably a psycho". HPW was 47 years of age and had no history of
27 criminal convictions. HPW had been in the army for some time before being discharged in 2007 after
28 failing to return some hand grenades. HPW had two children from a marriage which lasted more than
29 10 years. He subsequently had a relationship with another women which involved bestiality and anal
30 sex. Following assessment with a psychologist, it was considered that when "he realised what he was
31 doing" he immediately ceased the offending with his daughter. HPW only received a diagnosis of AD
32 after the criminal charges were laid. It was the view of the Psychologist, Dr Kennedy, that HPW had
33 no appreciation or understanding of the negative impact his actions were having on his daughter while
34 he was carrying out his offending. However, Dr Kennedy stated that following appropriate support,
35 HPW had since acquired both empathy and remorse which was believed to be genuine. HPW had not
36 engaged in any grooming process which is something which is comming found in cases of sex
37 offending. During the sentencing decision, the court did not consider HPW's diagnosis of AD had any
38 impact on his moral blameworthiness. However, the court did accept that his diagnosis of AD was a
39 mitigating factor in that it was likely to be more of a burden for his when it came to him to his custodial
40 sentence experience (see Allely, 2015). It ordered an increase to his sentence from seven and a half

9

10
11 Jones (2007) briefly discussed the case of a young man with ASD who was engaging in
12 bestiality. He was meeting people on online and making arrangement to visit their homes in order to
13 have intercourse with their pets. He does not appreciate or fully understand the potential risks of going
14 into strangers' homes as a result of his ASD. Jones highlights in the brief discussion of this case that
15 nothing legally could be done regarding the risks for this young man with ASD given that he was not
16 a minor (Jones, 2007). Lastly, Hellemans and colleagues (2010) carried out a study involving group
17 home caregivers of 20 institutionalised, male adolescents and young adults with Autistic Disorder
18 (AD) and borderline/mild mental retardation (MR) and another group comprising of group home
19 caregivers of 19 institutionalised, male adolescents and young adults with borderline/mild MR, without
20 AD. Both groups were interviewed using the Interview Sexuality Autism-Revised (ISA-R). Findings
21 revealed that in the group with AD there were some deviant sexual behaviours including stereotyped
22 sexual interests; sensory fascinations with a sexual connotation and paraphilia. However, no deviant
23 sexual behaviours were identified in the group with MR. Relevant to this review, Hellemans and
24 colleagues found one person with AD had several paraphilias including olfactophilia (which refers to
25 the paraphilia for, or sexual arousal by, smells and odours which come from the body, particularly in
26 the sexual areas), podophilia (a paraphilia which involves the sexual attraction to feet; foot fetishism)
27 and zoophilia (Hellemans et al., 2010).

43 **Discussion**

44
45
46 This systematic review is the first to explore the literature for any empirical study, case study or
47 discussion/review paper surrounding individuals with ASD and zoophilia or bestiality. The review
48 revealed a dearth of literature in the field. It identified only one article which was relevant in the
49 present review in that the association between zoophilia and ASD was the focus of the paper
50 (Chandradasa & Champika, 2017), three further articles were identified which included a description
51 of a case involving someone with ASD who engaged in zoophilia or bestiality (Jones, 2007;
52 Freckelton, 2013; Kellaher, 2015) and another paper, although not the focus of the study, found one
53 person with AD who had several paraphilias including olfactophilia, podophilia and zoophilia in a
54

3 sample of 20 institutionalized, male adolescents and young adults with Autistic Disorder (AD) and
4 borderline/mild mental retardation (MR) (Hellemans, Roeyers, Leplae, Dewaele, & Deboutte, 2010).
5
6
7

8 All the case studies clearly highlight some of the ASD symptomology that can contribute to
9 engaging in bestiality or zoophilia. ASD could be associated with zoophilia in a number of ways. For
10 instance, ASD could be associated with sexual interest in animals as a highly restricted fixated interest
11 that is abnormal in intensity which is related to criteria three in the second domain of the ASD
12 diagnostic criteria: ‘B Restricted repetitive patterns of behavior, interests, or activities’ (namely, B3
13 Highly restricted, fixated interests that are abnormal in intensity or focus; (such as strong attachment
14 to or preoccupation with unusual objects, excessively circumscribed or perseverative interests) (DSM-
15 5, 2013). Also, it could be related to the 3rd criteria of the first domain of the ASD diagnostic criteria
16 in which the person has deficits in developing and maintaining social relationships (specifically, A3
17 Deficits in developing and maintaining relationships, appropriate to developmental level (beyond those
18 with caregivers); ranging from difficulties in adjusting behavior to suit different social contexts
19 through difficulties in sharing imaginative play and in making friends to an apparent absence of interest
20 in people) (DSM-5, 2013). This deficit may prevent some individuals with ASD of having normal
21 intimate and sexual relationships with other humans. Critically, this lack of (or reduced) opportunity
22 to have normal sexual relationships between humans might lead to an increase in other forms of sexual
23 expression (Dr Miyuru Chandradasa, 2019, personal communication). In addition, we need to consider
24 the possible association with comorbid intellectual disability in a significant proportion of individuals
25 with ASD. The case report in paper by Chandradasa and Champika (2017) was on a person with high
26 functioning ASD (Dr Miyuru Chandradasa, 2019, personal communication). It would be useful to
27 investigate zoophilia and bestiality in individuals with ASD and intellectual disability as well as
28 individuals with “pure” ASD. It is well-established that there is a high co-morbidity between ASD and
29 intellectual disability (e.g., Matson & Shoemaker, 2009).

40
41
42
43
44
45
46

47 It is also important to consider that “having highly restricted interests and having sensory
48 peculiarities in ASD may possibly set the stage for developing fetishism and other paraphilias in
49 individuals with certain sensory profiles among other factors” (Kellaher, 2015, pp. 30). These highly
50 restricted interests related to the third criteria in first domain of the ASD diagnostic criteria, namely,
51 ‘B4 Hyper- or hypo-reactivity to sensory input or unusual interest in sensory aspects of environment;
52 (such as apparent indifference to pain/heat/cold, adverse response to specific sounds or textures,
53 excessive smelling or touching of objects, fascination with lights or spinning objects)’ (DSM-5, 2013).
54 Take the relevant case described by Kellaher (2015), which involved the young man with ASD whose
55
56
57
58
59
60

1
2
3 interest in wolves as a child transformed into a preferential canine zoophilia as an adolescent. This
4 young man had admitted that he was sexually excited at seeing and touching the fur and scrotum of a
5 large wolf-like dog. This is an example of an interest in the sensory parts of ‘the whole’ for sexual
6 excitement. Kellaher argues that this partialism or body part fetishism (which is ‘part’ oriented as
7 opposed to ‘whole’ other person-oriented) is relatively commonly identified in individuals with ASD.
8 So, for instance, “just as an ASD individual may be interested in the wheels of a car, he may also be
9 drawn sexually to the feet or hair of another person” (Kellaher, 2015, pp. 30). Indeed, this is consistent
10 with a number of published case studies involving individuals with ASD who have a paraphilia or
11 sexual interest in a particular body part such as feet (e.g., Dozier et al., 2011). Diagnosing cases of
12 paraphilic disorders (such as zoophilia) in individuals with ASD can be challenging. One of the main
13 reasons for this is that specific behaviours can be stimulated by sensory (and other) disorders, with no
14 sexual element being involved. However, restricted, repetitive interests and behaviors which have no
15 sexual element in childhood may, in adolescence, develop into sexualised or sexual, restricted,
16 repetitive interests. In other words, “early, inadvertent conditioning to sensory stimuli that is appealing
17 during pre-puberty may lead to a powerful union between specific ASD sensory-seeking and sexual
18 arousal through masturbation” (Kellaher, 2015, pp. 30). The idea of early conditioning to deviant
19 stimuli has been discussed before (Singh & Coffey, 2012). However, it has never been examined as a
20 factor by itself and studied empirically (Kellaher, 2015; Kellaher, 2019, personal communication).

31
32
33
34
35

36 As highlighted by Kellaher (2015), it is possible that deviant sexual behaviour, such as
37 zoophilia, may be the result of a paraphilia. However, it is also important to consider whether such
38 behaviours represent “counterfeit” deviant sexual behaviour in individuals with ASD. Counterfeit
39 deviance is a term which is used to describe sexual behaviour that seems to arise from a paraphilia but
40 may actually stem from impaired social skills and a lack of sexual knowledge and experience
41 (Hingsburger, Griffiths, & Quinsey, 1991) relating to criteria one in the first domain of the ASD
42 diagnostic criteria: ‘A1 Deficits in social–emotional reciprocity; ranging from abnormal social
43 approach and failure of normal back and forth conversation through reduced sharing of interests,
44 emotions, and affect and response to total lack of initiation of social interaction’ (DSM-5, 2013). The
45 issue of counterfeit deviant sexual behaviour stemming from social skills impairments has previously
46 been explored in the literature, typically in relation to sex-offending behaviour (Griffiths, Hingsburger,
47 Hoath, & Ioannou, 2013). Take the example of a young man with ASD who obsessively collects female
48 silk undergarments may have no sexual interest in the collection, though it would be considered to
49 sexually motivated by others (Kellaher, 2015). Further support for this argument comes from a study
50 by Beetz (2002) who examined a community sample of 113 men and three women who had all reported
51

12 *Clinical Implications and Recommendations*

13

14
15 As mentioned briefly in the introduction, individuals with ASD often experience prejudicial
16 stereotypes that they are asexual, hyper- or hypo sexual, child-like and dependent, and/or uninterested
17 in sex (Bennett, Webster, Goodall, & Rowland, 2018; MacKenzie, 2018). Also, MacKenzie (2018)
18 have also highlighted that their sexuality is considered by some be problematic and needs to be
19 ‘treated’ or managed. Some of the stereotypes surrounding the sexuality of individuals with ASD are
20 perpetuated by some of the features of ASD such as aversion to being touched by others and that
21 because they are ‘unemotional’ they would not be interested in sexual relationships (Kellaher, 2015;
22 MacKenzie, 2018). As young people with ASD enter into adulthood, they may find themselves faced
23 with significant difficulties in developing and maintaining social and romantic relationships as a result
24 of their social impairments and sexual ‘anomalies’ (Henault & Attwood, 2006; MacKenzie, 2018).
25
26
27
28
29
30
31
32
33

34 It has been argued that the lack of support and services (in schools, etc) to help autistic adults
35 with ASD develop the necessary skills to help them understand the social nuances of dating, intimacy
36 and relationships further exacerbate these difficulties faced by individuals with ASD (MacKenzie,
37 2018). Individuals with ASD are much less likely to be able to get sexual health information from their
38 friends or peer groups, media, school and parents (Bleakley, Hennessy, Fishbein, & Jordan, 2009).
39 Adolescents with ASD frequently do not have links with extensive peer groups where informal
40 discussions relating to sex occur (Mehzabin & Stokes, 2011). It has also been identified that individuals
41 with ASD are less likely to receive sex and sexuality education, or an education in sex and social
42 relationships that is tailored to their specific needs (MacKenzie, 2018). Moreover, there is an
43 increasing number of studies indicating that individuals with ASD are also less likely to gain
44 knowledge about sex from their parents or teachers. It has also been suggested that they more often
45 access the media and pornography in an attempt to gain information about sex. This can often lead to
46 unintentional online offending in some cases (see Allely & Dubin, 2018). Many individuals with ASD
47 have insight into their own impairments in relation to romantic relationships which has an adverse
48 impact on their social relationships (Stokes, Newton, & Kaur, 2007; Brown-Lavoie, Viecili, & Weiss,
49 2014; Barnett & Maticka-Tyndale, 2015; Parchomiuk, 2018).

57
58
59
60

1
2
3
4
5 In a survey with individuals with ASD and typically developing individuals, Mehzabin and
6 Stokes (2011) found that individuals with ASD have less adaptive sexual knowledge and behaviours,
7 reported less social behaviour (e.g., going out with friends), less education about sex and sexuality and
8 less sexual experience (Mezhabin & Stokes, 2011). In a study by Corona and colleagues (2016)
9 findings suggested that parents of adolescents with ASD believe that their children are interested in
10 sexual and romantic relationships. However, they are not aware of how to effectively and appropriately
11 instigate conversations with their child with ASD regarding such topics (Corona, Fox, Christodulu, &
12 Worlock, 2016). As highlighted by Corona and colleagues (2016), there is a general consensus that
13 adolescents with ASD need to be able to access education about sexuality and relationships needs
14 (Travers & Tincani, 2010; Chan, & John, 2012; Gilmour, Smith, & Schalomon, 2014; Sullivan &
15 Caterino, 2008). The education would consist of the core topics covered in standard sex education
16 programmes (e.g., sexual development, safe sex, contraception, and sexually-transmitted infections)
17 in addition to topics such as: social skills development (e.g., empathy, perspective-taking) and social
18 conventions relating to flirting and dating (Travers & Tincani, 2010; Chan, & John, 2012; Gilmour,
19 Smith, & Schalomon, 2014).

29
30
31

32 In their semi-structured qualitative interviews with 18 parents of children with ASD (aged 6–
33 13 years), Ballan (2012) found that some parents believed that broad-ranging discussions about
34 sexuality and relationships would not be relevant. Parents reported that their sexuality-related
35 discussions with their child did not include topics relating to their child's future social and sexual
36 behaviours (Ballan, 2012). Consistent with this, in the study by Mackin and colleagues (2016) they
37 found that *few* parents of children with ASD could quickly imagine the likelihood of their child ever
38 experiencing a romantic relationship (Mackin, Loew, Gonzalez, Tykol, & Christensen, 2016). Based
39 on focus groups with parents of children and adolescents with ASD, Nichols and Blakeley-Smith
40 (2009) found that the parents shared the same concerns such as worrying about their child with ASD
41 facing legal problems as a result of their own actions. Additionally, confusion surrounding what
42 healthy sexuality might look like in someone with ASD was also reported by some of the parents
43 (Nichols & Blakeley-Smith, 2009).
44
45
46
47
48
49
50
51
52
53
54

55 It is unsurprising that parents of children with ASD across the autism spectrum experience such
56 difficulties in their sexuality-related discussions with their child given that it is common for parents of
57 typically developing children to report that they put off or neglected discussing sex related topics with
58 their child because of feelings of discomfort, their perceived inadequate or inaccurate knowledge, etc
59
60

1
2
3 (Croft & Asmussen, 1992). However, for parents of youth with ASD it could be even more challenging
4 and important. One of the reasons for this is the discrepancy between chronological age and
5 developmental age (Holmes, Himle, & Strassberg, 2016). Also, if they expect their child will never
6 have a sexual relationship(s) and/or if the parents expect that their child will not need or gain anything
7 from sexuality and relationship education, parents of children with ASD may be reluctant to engage in
8 sexuality interactions with their child (e.g., Ivey, 2004; Holmes et al., 2016). There may also been
9 feelings of shame upon discovery of their child with ASD engaging in some form of bestiality and the
10 need to hide the issue. The need to provide support to parents of children with ASD as they navigate
11 through the challenges relating to sexuality and relationship education cannot be stressed enough
12 (Ballan, 2012). Nichols and Blakeley-Smith (2009) amongst others, have highlighted that parents and
13 professionals need to collaborate when delivering this education (Travers & Tincani, 2010).
14 Unfortunately, there is relatively little empirical research which have been carried out to date on
15 programmes which are specifically tailored to address this need (Corona, Fox, Christodulu, &
16 Worlock, 2016).
17

31 *Future Research Directions*

32
33 There are numerous studies which have found that individuals who engage in zoophilic behaviours are
34 at increased risk of perpetrating other criminal offenses (e.g., Fleming, Jory, & Burton, 2002; Hensley,
35 Tallichet, & Singer, 2006; Hensley, Tallichet, & Dutkiewicz, 2010). It has been suggested that
36 zoophilic acts may be a potential useful indicator for future risk of sexual and also nonsexual violent
37 behaviour (Holoyda & Newman, 2014). Moreover, Abel carried out a survey of 44,202 adult men and
38 found that the single strongest predictor for engaging in future child sexual abuse was a history of
39 bestiality (Abel, 2008). Another study found childhood bestiality to be the only method of animal
40 cruelty which was able to predict future 'recurrent interpersonal violence' (Henderson et al., 2011).
41 However, Ranger and Fedoroff (2014), amongst others, have emphasised the potential limitations of
42 the literature to date. For instance, most studies on bestiality and violence risk comprise of forensic
43 samples with no control groups (Holoyda et al., 2016). Future studies need to address this and also
44 explore the violence risk in individuals with ASD who engaged in bestiality.
45
46
47
48
49
50
51
52
53
54

55 As highlighted by Hellemans and colleagues (2011), there is a need for more research
56 investigating the prevalence of paraphilia, in particular zoophilia (as well as bestiality) in persons with
57 ASD. Also, more researched is needed surrounding the development and evaluation of specifically
58
59
60

1
2
3 tailored sexuality education programmes which help promote positive transitions for adolescents with
4 ASD (Corona, Fox, Christodulu, & Worlock, 2016).

7
8
9

10 **Conclusions**

11
12
13 This systematic review highlighted only a small number of papers which have looked at zoophilia or
14 bestiality in individuals with ASD. It is crucial that there are more case studies and empirical
15 investigations into this area in order to gain more of an understanding of how ASD symptomology can
16 contribute to paraphilias such as zoophilia and also the role they may play in bestiality. The knowledge
17 gained from such research will help increase our understanding of how certain features of ASD may
18 contribute to such behaviours. Also, it will help aid identification of such behaviours in individuals
19 with ASD and also inform the develop of appropriate interventions/treatments. As also highlighted in
20 the clinical implications and recommendations section it is important that individuals with ASD have
21 access to appropriate and timely sex education and that parents are supported by healthcare
22 professionals to engage with their children with ASD in such interactions across the autism spectrum
23 irrespective of the parent's expectations (Holmes, Himle, & Strassberg, 2016).
